# Functions of Mammalian Cerebral Cortex and Thalamus (Thalamocortex)

- Object (perceptual, motor, conceptual, thought process, abstract, etc.) representation
- Learning and storing knowledge about objects
- Thinking
- Participation (with subcortical structures) in control of movement and thought

# How Does Cerebral Cortex Represent Objects?

Human cerebral cortex is tiled with over a hundred thousand *regions* -- each forming the upper half of a **FEATURE ATTRACTOR** neuronal network

A feature attractor network

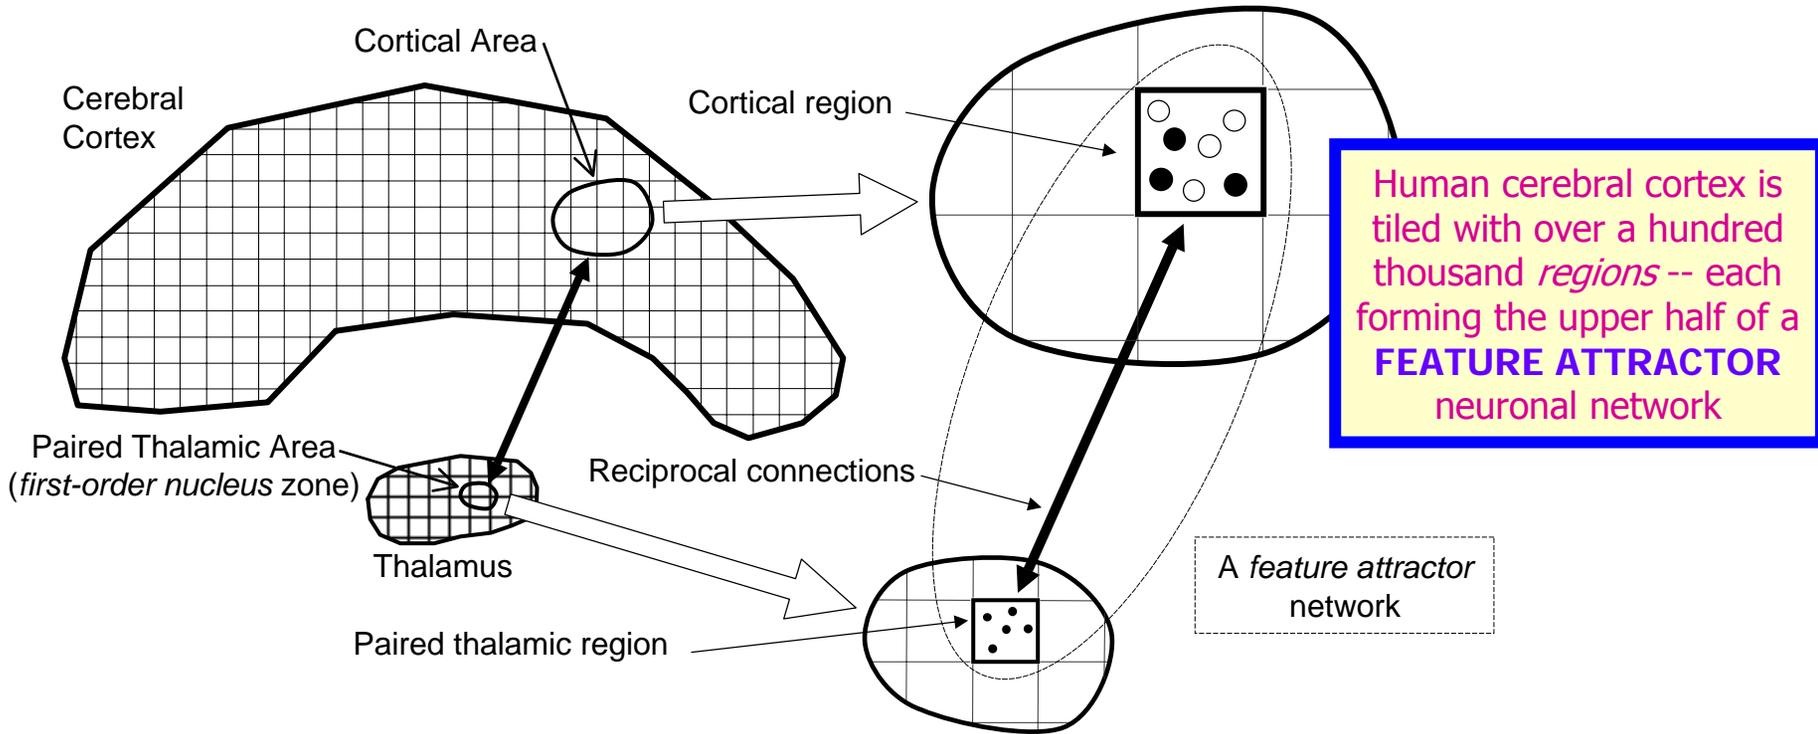

Each cortical region becomes equipped with a *lexicon of standardized tokens* (frozen early in learning) which are used to describe one specific *attribute of an object*

$$\{\Phi, T_1, T_2, \dots, T_K\}$$

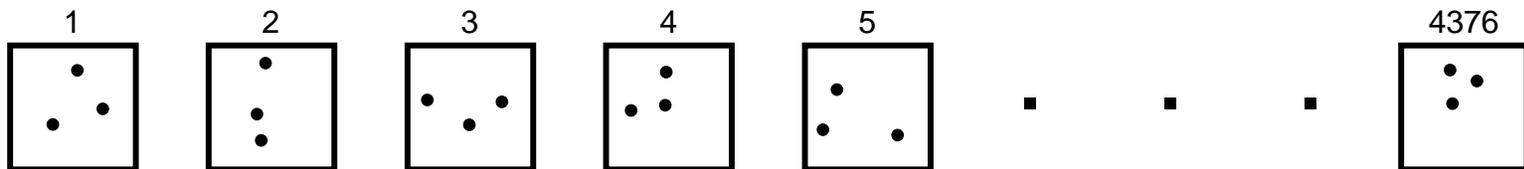

Neurons can randomly die and it still works.

**OBJECT ATTRIBUTES ARE FUNDAMENTALLY SYMBOLIC**

## How Does Cerebral Cortex Represent Objects?

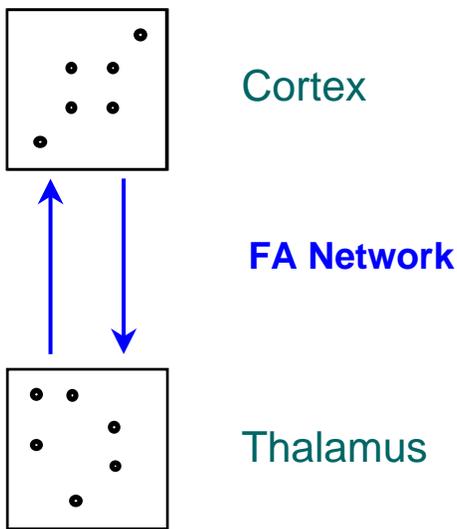

Each cortical region has a fixed *lexicon* of neuron tokens (each containing a few hundred neurons out of over 100,000). After each activation of the feature attractor network (or when external expectation input is supplied to the region in advance), the region rapidly ends up expressing **one and only one** of the lexicon tokens as its *active* output.

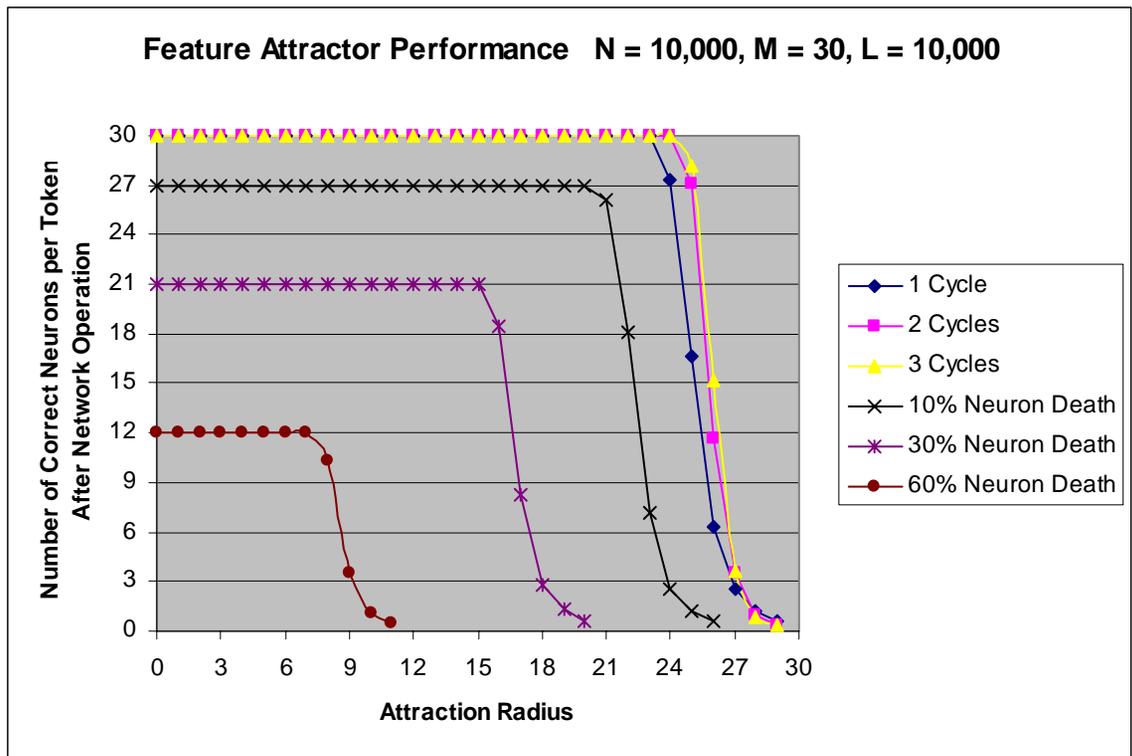

## How Does Cerebral Cortex Represent Objects?

The gradual random death of its neurons has no significant effect on feature attractor performance

### Feature Attractor Performance vs. Random Neuron Death

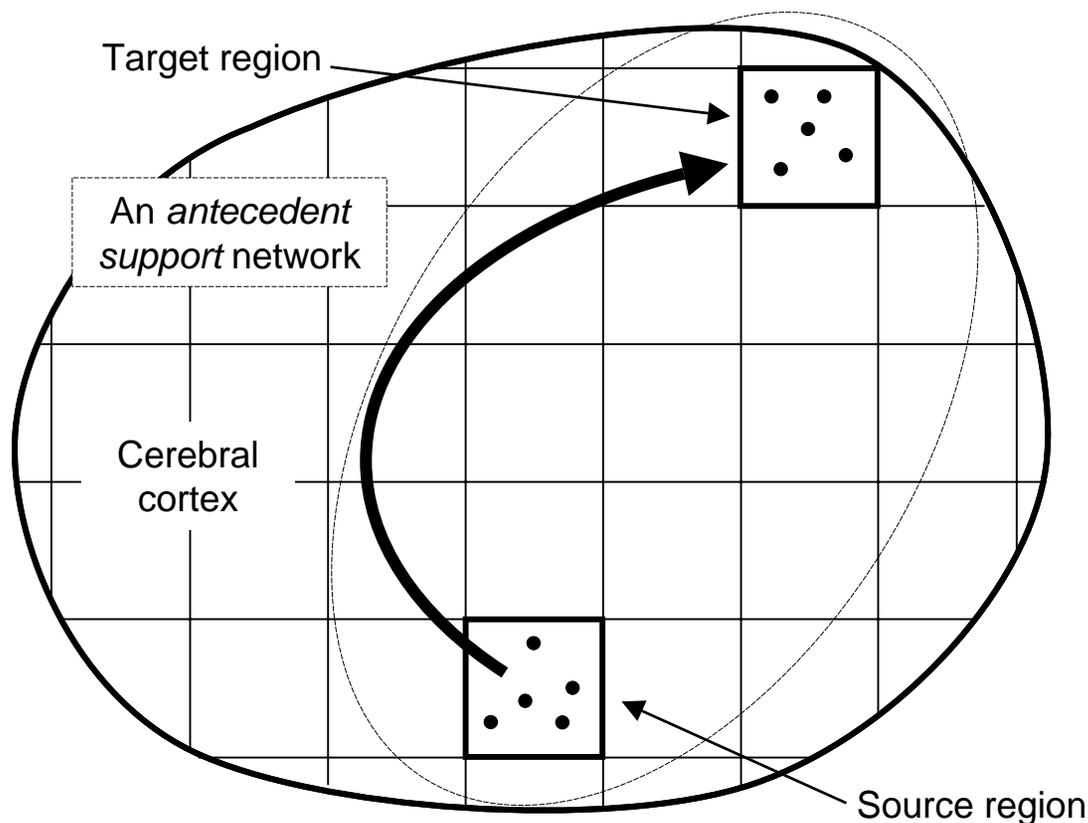

Thanks to Robert Means for this computer experiment

## How Does Cerebral Cortex Represent Objects?

- Each cortical region is responsible for describing one *attribute* of an object. That description is accomplished by activating one of its lexicon tokens (or none, the *null token*, if its attribute is not applicable or not needed).
- Feature attractors can accomplish their function almost instantly if expectation is present, which significantly restricts the selection of the winning token. Otherwise, operation of the feature attractor takes about a tenth of a second.
- The 120,000 regions of the human cerebral cortex provide the mechanism for describing any object that can be considered in terms of a collection of individual attribute tokens (*attribute descriptors*). Thus, this is a *symbolic* representation.

## How Does Cerebral Cortex Learn & Store Information?

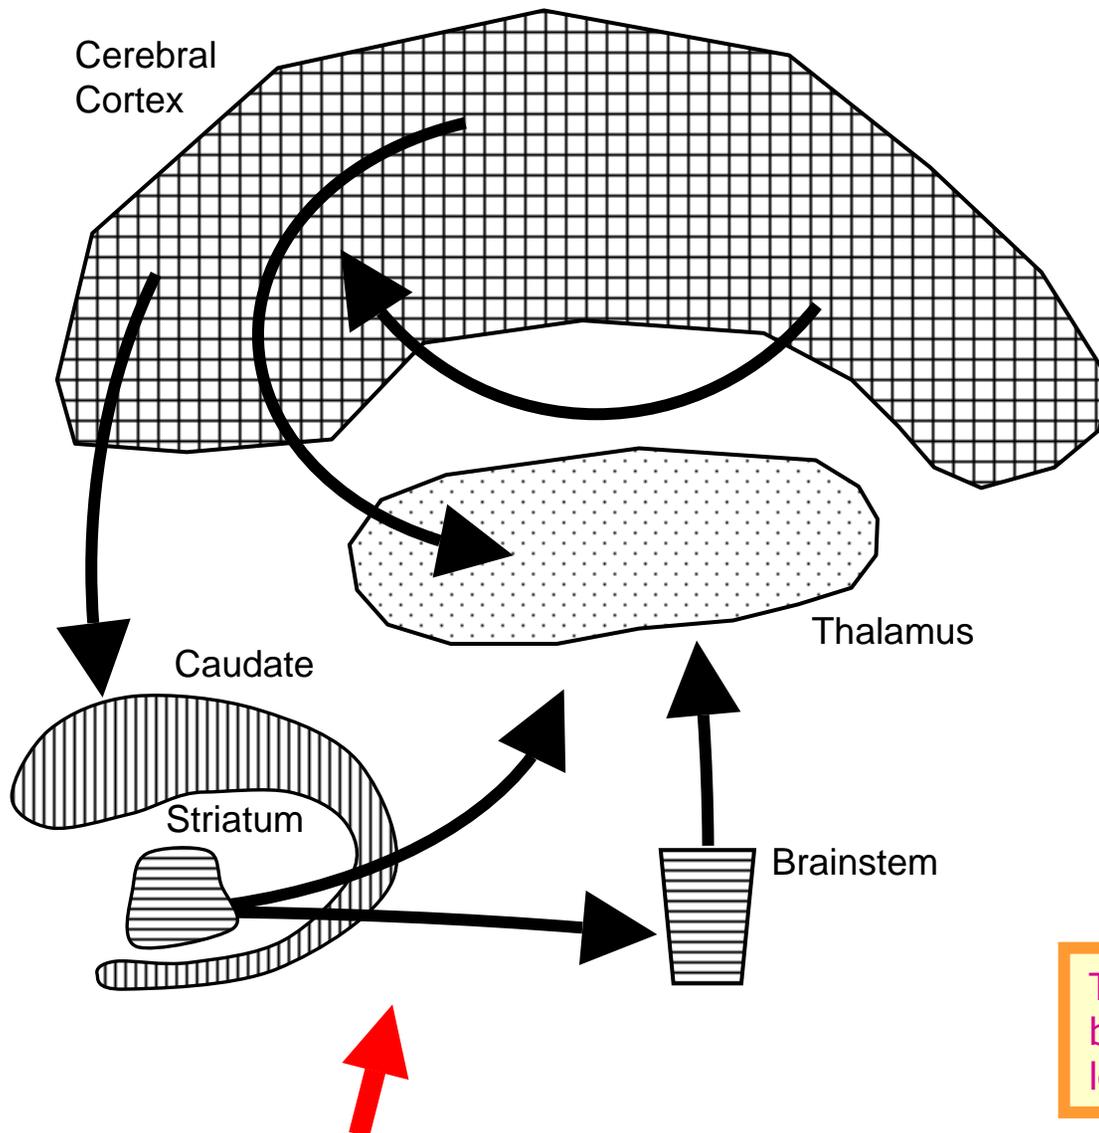

*Antecedent support* networks, of which there are hypothesized to be over a million in human thalamocortex, unidirectionally link each lexicon token of the network's cortical *source region* to *selected* lexicon tokens of its *target region*. The criterion for linkage selection is that the co-occurrence of source and target tokens  $i$  and  $j$  was, over some extensive set of sequential operations of the network, significantly above chance. If tokens  $i$  and  $j$  are to be linked, the weight of this linkage  $w(i,j)$  is a positive sigmoidal function of  $p(i,j)/p(j) = p(i|j)$  – a quantity called the level of *antecedent support* of  $i$ , given token  $j$ .

The link strengths  $w(i,j)$  of antecedent support networks are hypothesized to constitute the only information learned and stored in mammalian thalamocortex. Each antecedent support network can be viewed as a *knowledge base* concerning unidirectional relationships between the attribute description tokens expressed on its two regions.

## How Does Cerebral Cortex Learn & Store Information?

- The cerebral cortex acquires all antecedent support probabilities for token pairs which have (genetically determined) physiological links and which appear together sufficiently often over any period of N activations of the involved antecedent support network. In this sense, our knowledge is *exhaustive*.
- Once acquired, each item of knowledge is permanent (although the links very slowly weaken as a result of gradual neuron death) unless the usage of the source token changes radically, requiring the formation of many new linkages. This causes old, now disused, linkages of that source token to erode. This is how we know where the clock is in our new home and, eventually, forget where it was in our old home.
- The human cerebral cortex has a couple million antecedent support networks. Each source token is linked to, say, an average of a hundred target tokens. This implies a total human thalamocortical information storage of about 2 TBytes (= 27,892 average bits of information acquired every waking second over 30 years).

## Brain Control of Brain Function

### Movements and Thoughts are Siblings

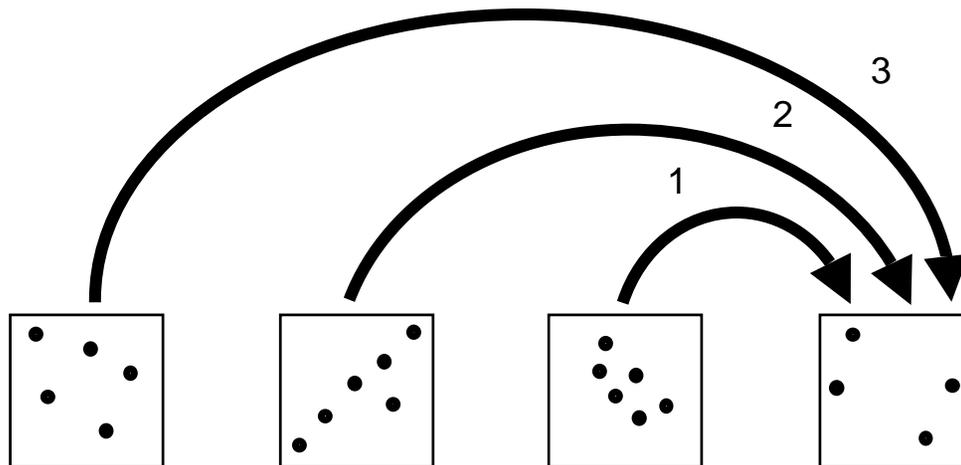

The *world state* (internal and external) is constantly being expressed and delivered across cortex, causing issuance of *actions* (movements and/or thoughts) from deep cortical layers. Layer 5 projections from primary motor cortex go to spinal motor nuclei. Layer 5 projections from the rest of cortex go to subcortical nuclei which control feature attractor and antecedent support network activations (just as if they were muscles).

The brain command loop can be entrained by, and phase locked to, music and dance.

The *brain command loop* (with many parallel streams) runs continuously during wakefulness

## Consensus Building: The Universal Thalamocortical Information Processing Operation

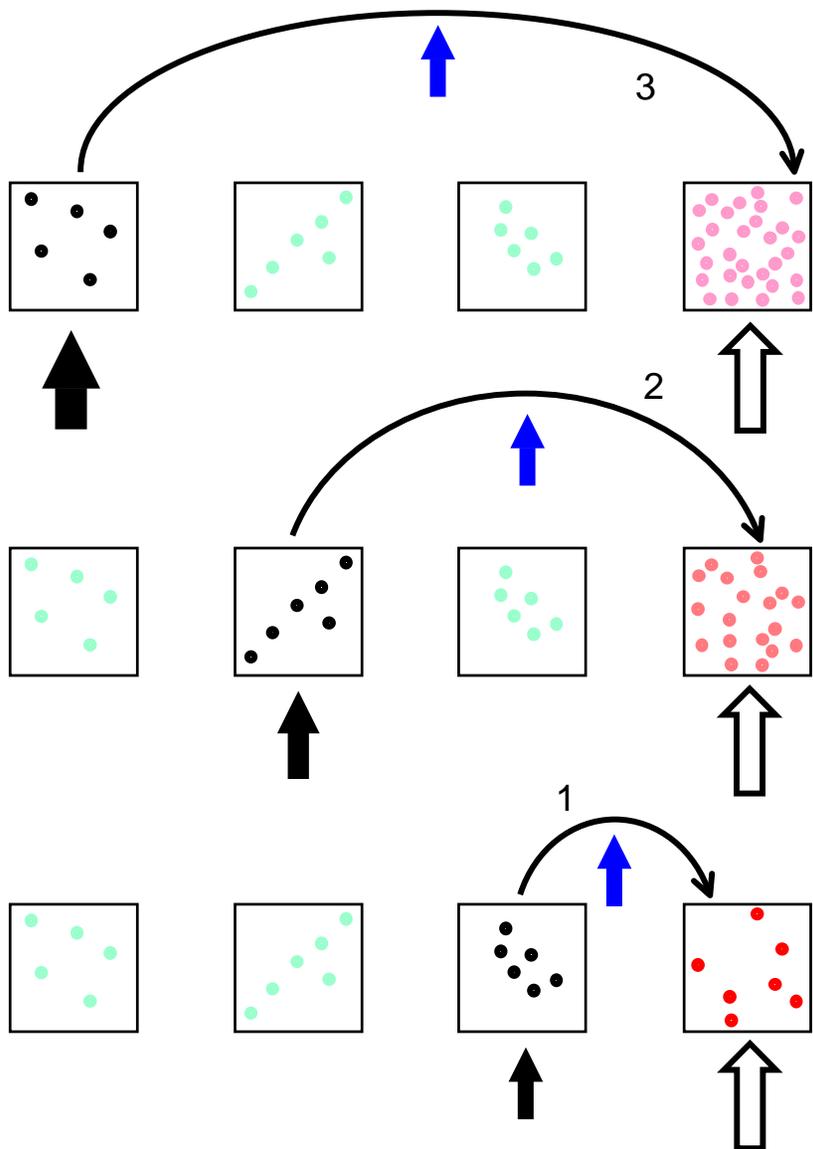

- **The Law of Mammalian Thought**: Choose that rational answer region token which maximally supports (in terms of  $p(i|j)$  value) the weakest item of evidence in its favor. In other words, choose that  $j$  which maximizes  $\text{MIN}[p(i_1|j), \dots, p(i_k|j)]$ .
- Only answer tokens which have links from all the *assumed facts* are considered.
- Consensus building is hypothesized to be carried out in a fraction of a second in thalamocortex via a local neuronal dynamical behavior called *honing*.
- This kind of attribute co-occurrence knowledge is comprehensive (exhaustive, actually) and robust, and thus ideal for dealing with real-life situations, which are almost always novel. This is in stark contrast to Aristotelian and Bayesian rules, which are narrowly specific in their scope of application.

## Key Attributes of the Cerebral Cortex

- Objects are described in terms of (non-unique) combinations of fixed-for-life *attribute descriptors*.
- Knowledge takes the form of pairwise rational *antecedent support* token pair linkages from one attribute descriptor to another.
- Cortical knowledge is *exhaustive* and *robust*.
- Thinking is extremely fast and yet implements a huge search which considers all rational alternatives and picks the best one.
- The 'best' answer is that one which maximally supports the weakest item of evidence in its favor. This is the *Law of Mammalian Thought*.

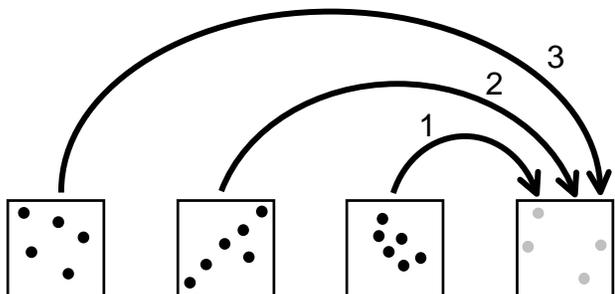

# Implementation of Consensus Building: *Honing*

Consensus building involves *sequential activation* of groups of regions in accordance with a specified *precedence ordering*. At each stage of this sequence, each answer region is *honed*. Honing involves turning off (for the remainder of the CB operation) those neurons which do not receive significance input above a fixed minimum. Neurons which remain on have their activation level set to their new significance input value; except that this level can never increase; only decrease, during the CB process. Additional answers can be discerned by turning off answer neurons and repeating the CB process. The entire CB process typically requires only a few hundred milliseconds.

CB is a stored *thought process* (region and fascicle activation sequence) which is data independent. Such thought processes are learned, stored, and issued by cortex exactly like movements.

# Consensus Building: Combining Knowledge

Knowledge Base 3: **driving**: influence, expired, suspended

Knowledge Base 2: **at**: university, time, A.M., P.M.

Knowledge Base 1: **top**: priority, aides, aid, executives

## Assumed Facts

## Consensus Answers

(from successive CB operations)

### legend

## Antecedent Support Network Connectivity Statistics

(typical: preword-postword)

Number of Words in the Lexicon	Number of Possible Links	Number of Actual Links	Percentage Connectivity
5,000	25,000,000	6,109,422	24.4%
10,000	100,000,000	11,438,063	11.4%
30,000	900,000,000	21,724,904	2.4%

# Other Simple Thought Process Examples

- Antecedent support knowledge bases contain both explicit and implicit knowledge about *word functionality* (semantics, grammar, etc.).
- For example, consider the following knowledge bases and the sentence template:

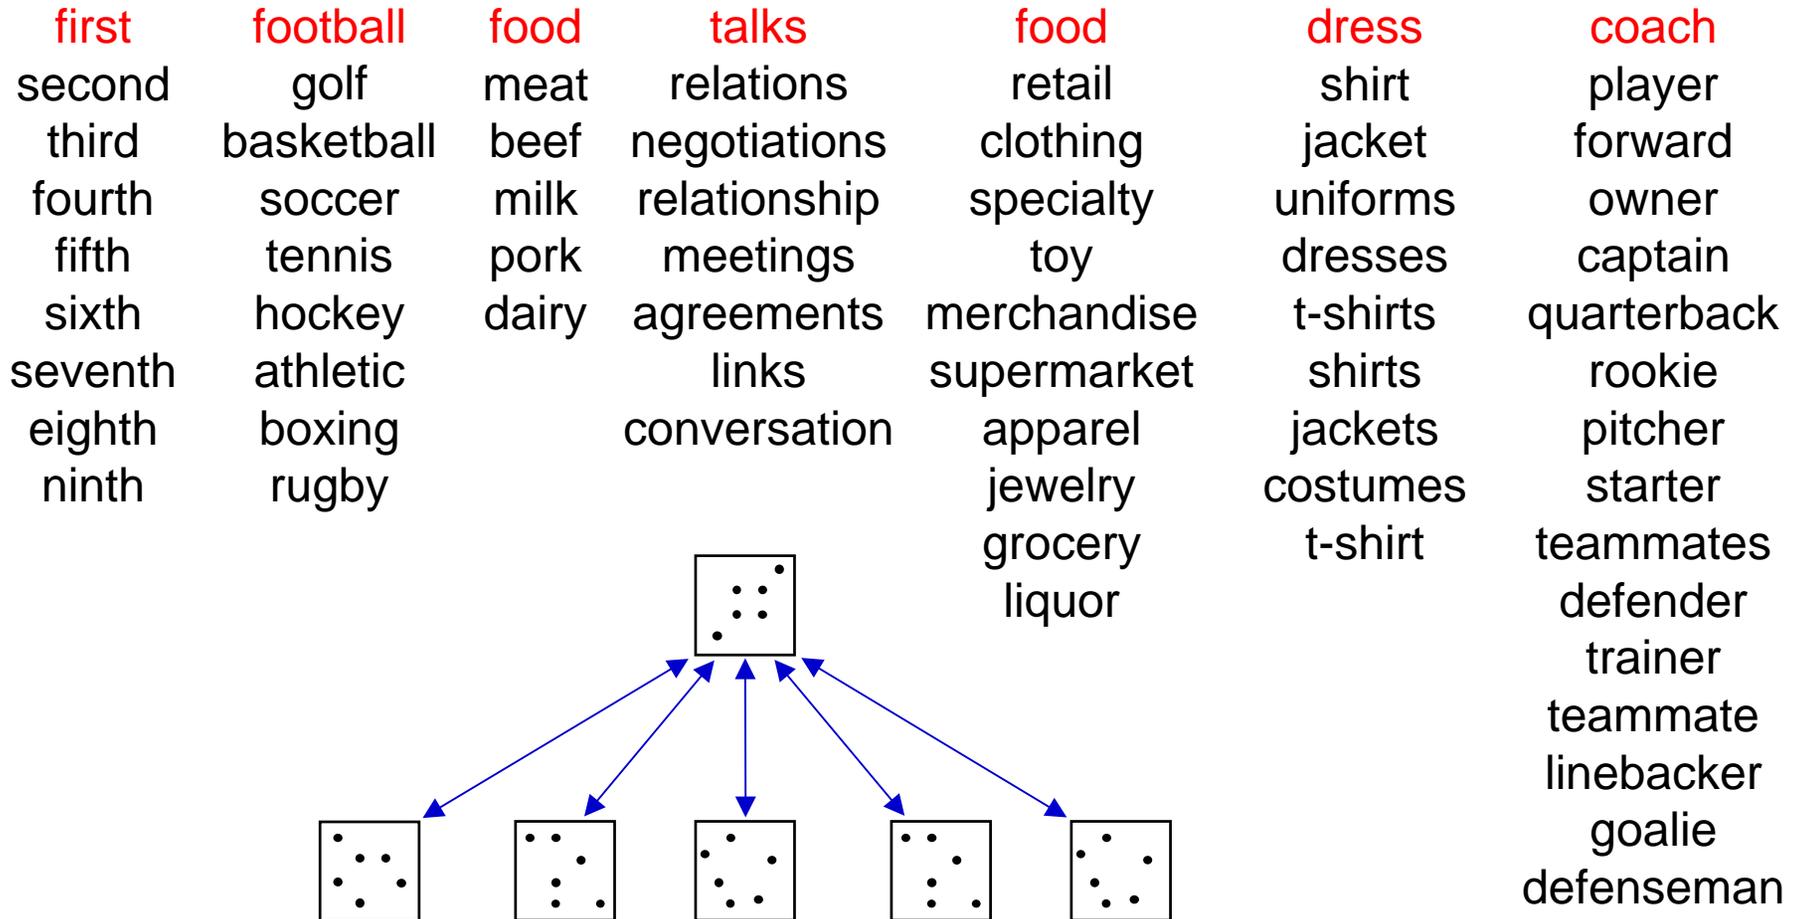

**A \* ??? well.**

- **President:** speaks, travels, understands, defended
- **Quarterback:** throws, recruit, draw, threw
- **Car:** coat, ran, speeds, stops, handles
- **Model:** wears, sells, oh, fits, dressed
- **Person:** executed, ate, understands, feels, knows
- **Teacher:** taught, training, travels, pay, speaks

**A \* can ???.**

- **Person:** swim, die, fly, sail, commit
- **Dog:** bite, hunt, duck, pig, eat
- **Fish:** swim, bite, feed, fish, hunt
- **President:** veto, appoint, consult, propose, testify
- **Jury:** decide, hear, spare, reasonably, consider
- **Judge** dismiss, appoint, decide, declare, impose

## Word *Families*: The Emergence of Abstraction

A simple automated process produced 18,339 families for a lexicon of 10,000 words. Each family is a subset of the *synonymy set* of that word. Families are like word senses, but more abstract and more useful. For example, word family matching between sentences can be used to evaluate their similarity of meaning

# Families for Sentence Meaning Comparison

1: **They** brought a **lawsuit** against **Firestone**.

2: **We** filed a **case** charging **Michelin** of wrongdoing.

**This example illustrates the vast context-exploitation power of this new approach to information processing**

# Families for Sentence Meaning Comparison

1: The **safety** personnel ran out to the shuttle immediately after **touchdown**.

safety  
medical  
legal  
accounting  
scientific  
security  
regulatory  
investigative  
...

safety  
quarterback  
linebacker  
defenseman  
goalie  
owner  
coach  
starter  
forward  
rookie  
...

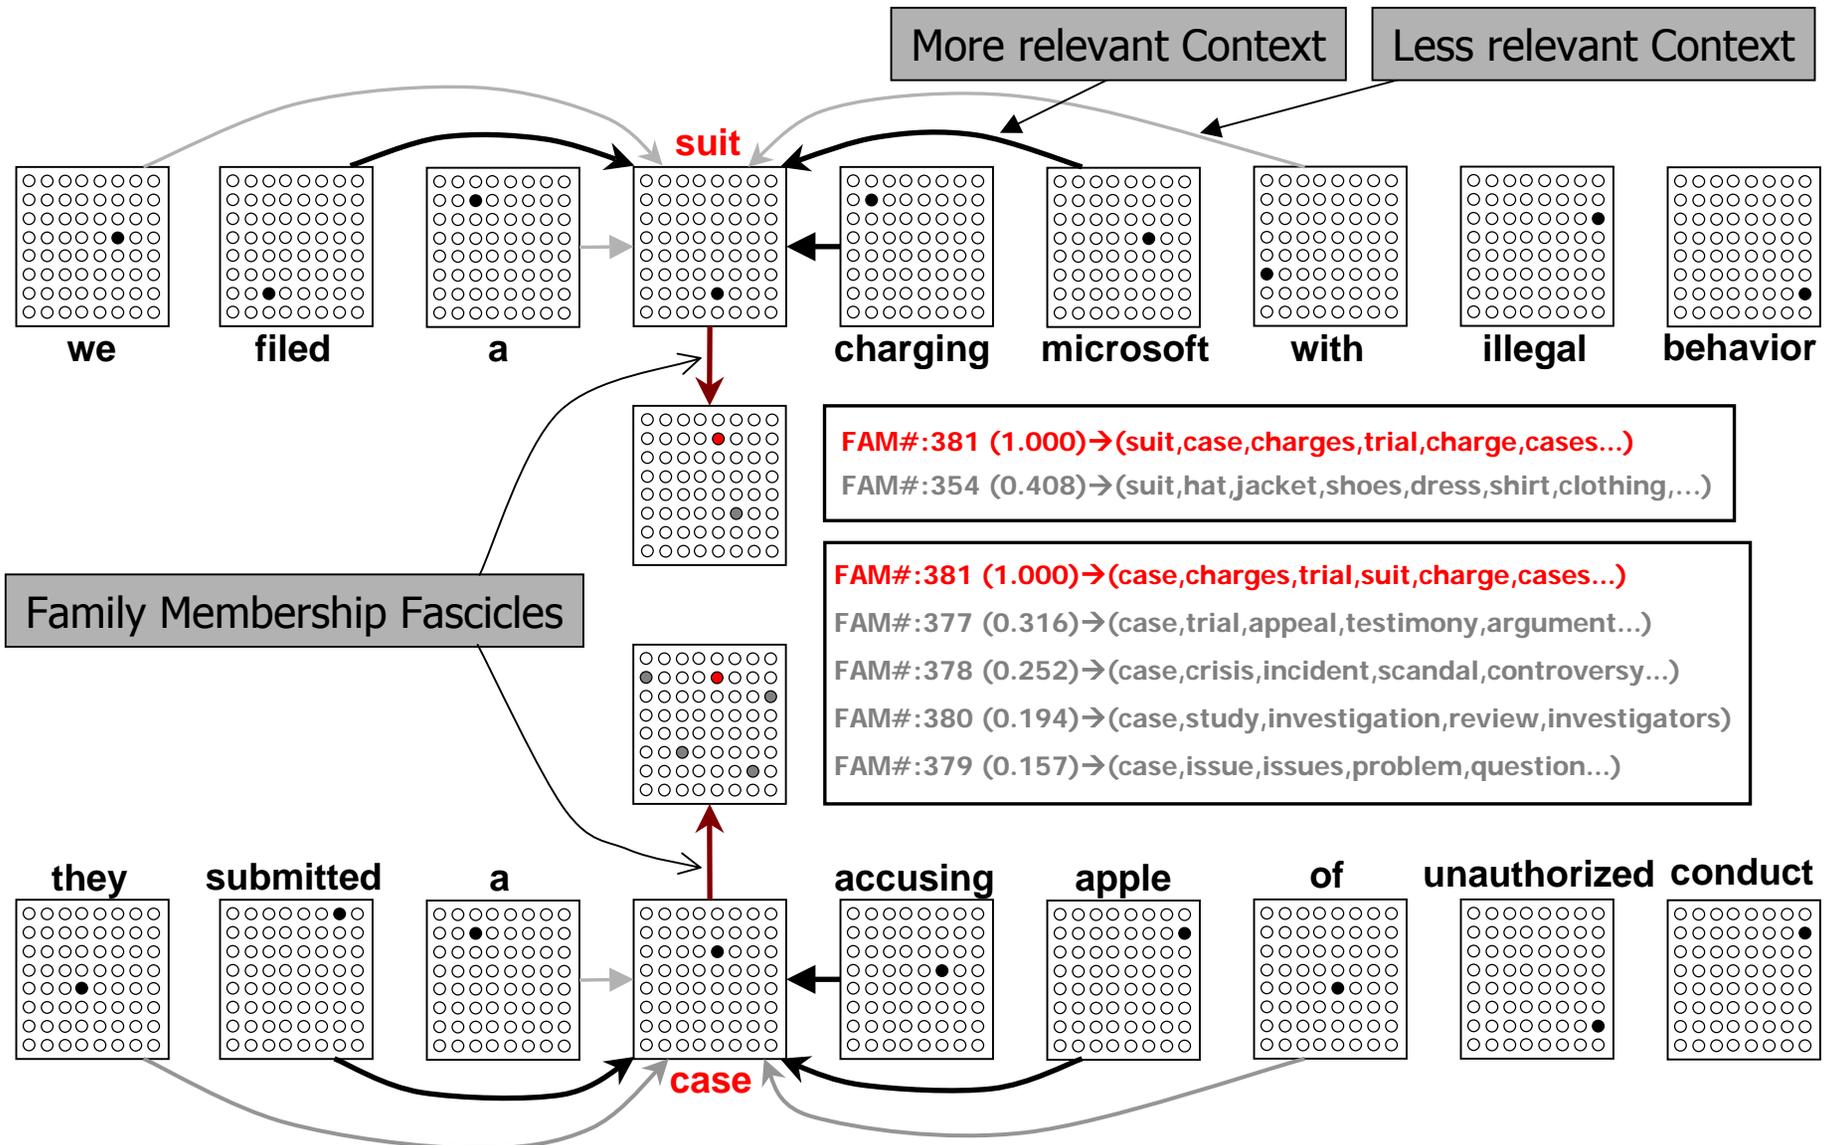

*Similarly, 'touchdown' can be disambiguated into "landing" and "goal", respectively, leaving wholly distinct sentence representations (and therefore small similarity measure).*

2: The team's **safety** scored a **touchdown**.

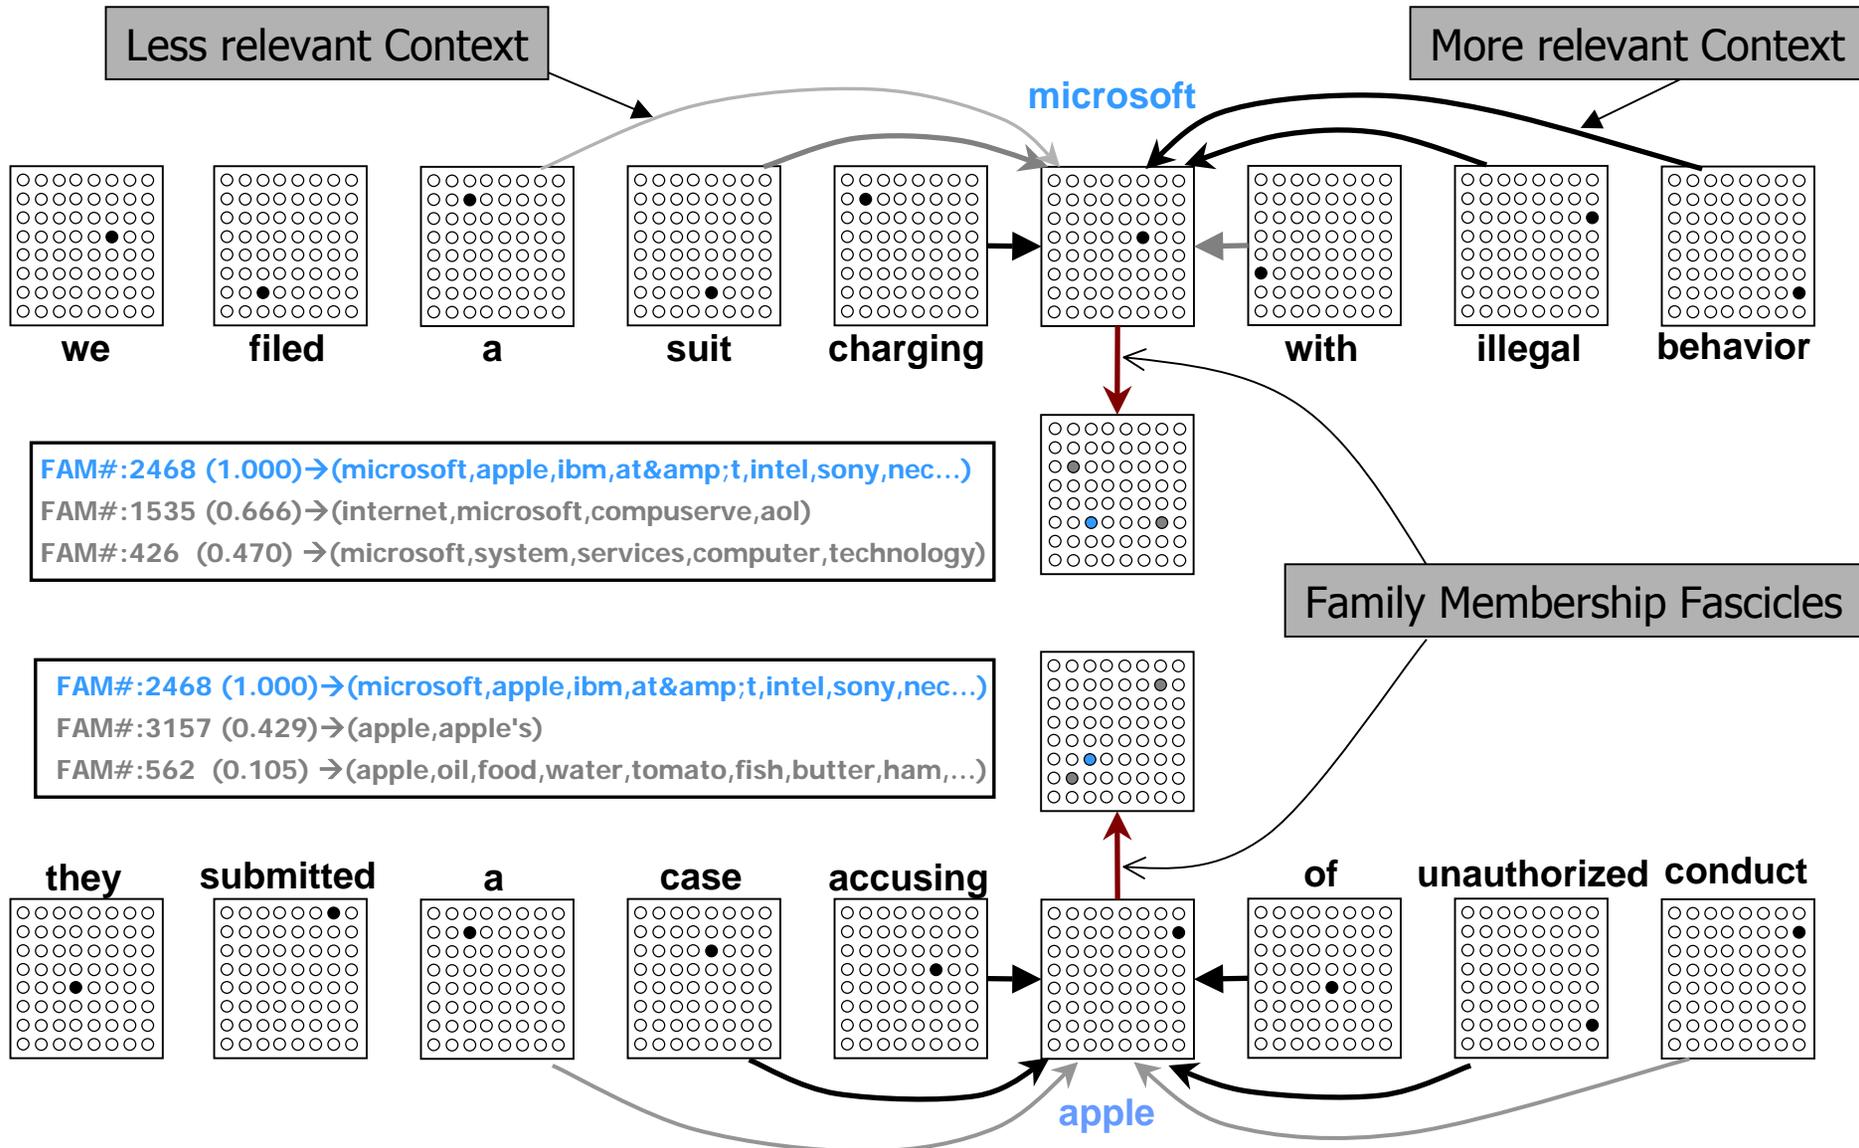

# Test Sentence Pairs

- No common words, similar meaning
  - we **filed** a **suit** **charging** **microsoft** with **illegal** **behavior**
  - they **submitted** a **case** **accusing** **apple** of **unauthorized** **conduct**
    - SIMILARITY = 0.995
- Some common words, dissimilar meaning
  - i was **right** to avoid a **suit** against **apple**
  - on my **right** was a man in a **suit** drinking **apple** juice
    - SIMILARITY = 0.171

## Context-Driven Family Disambiguation

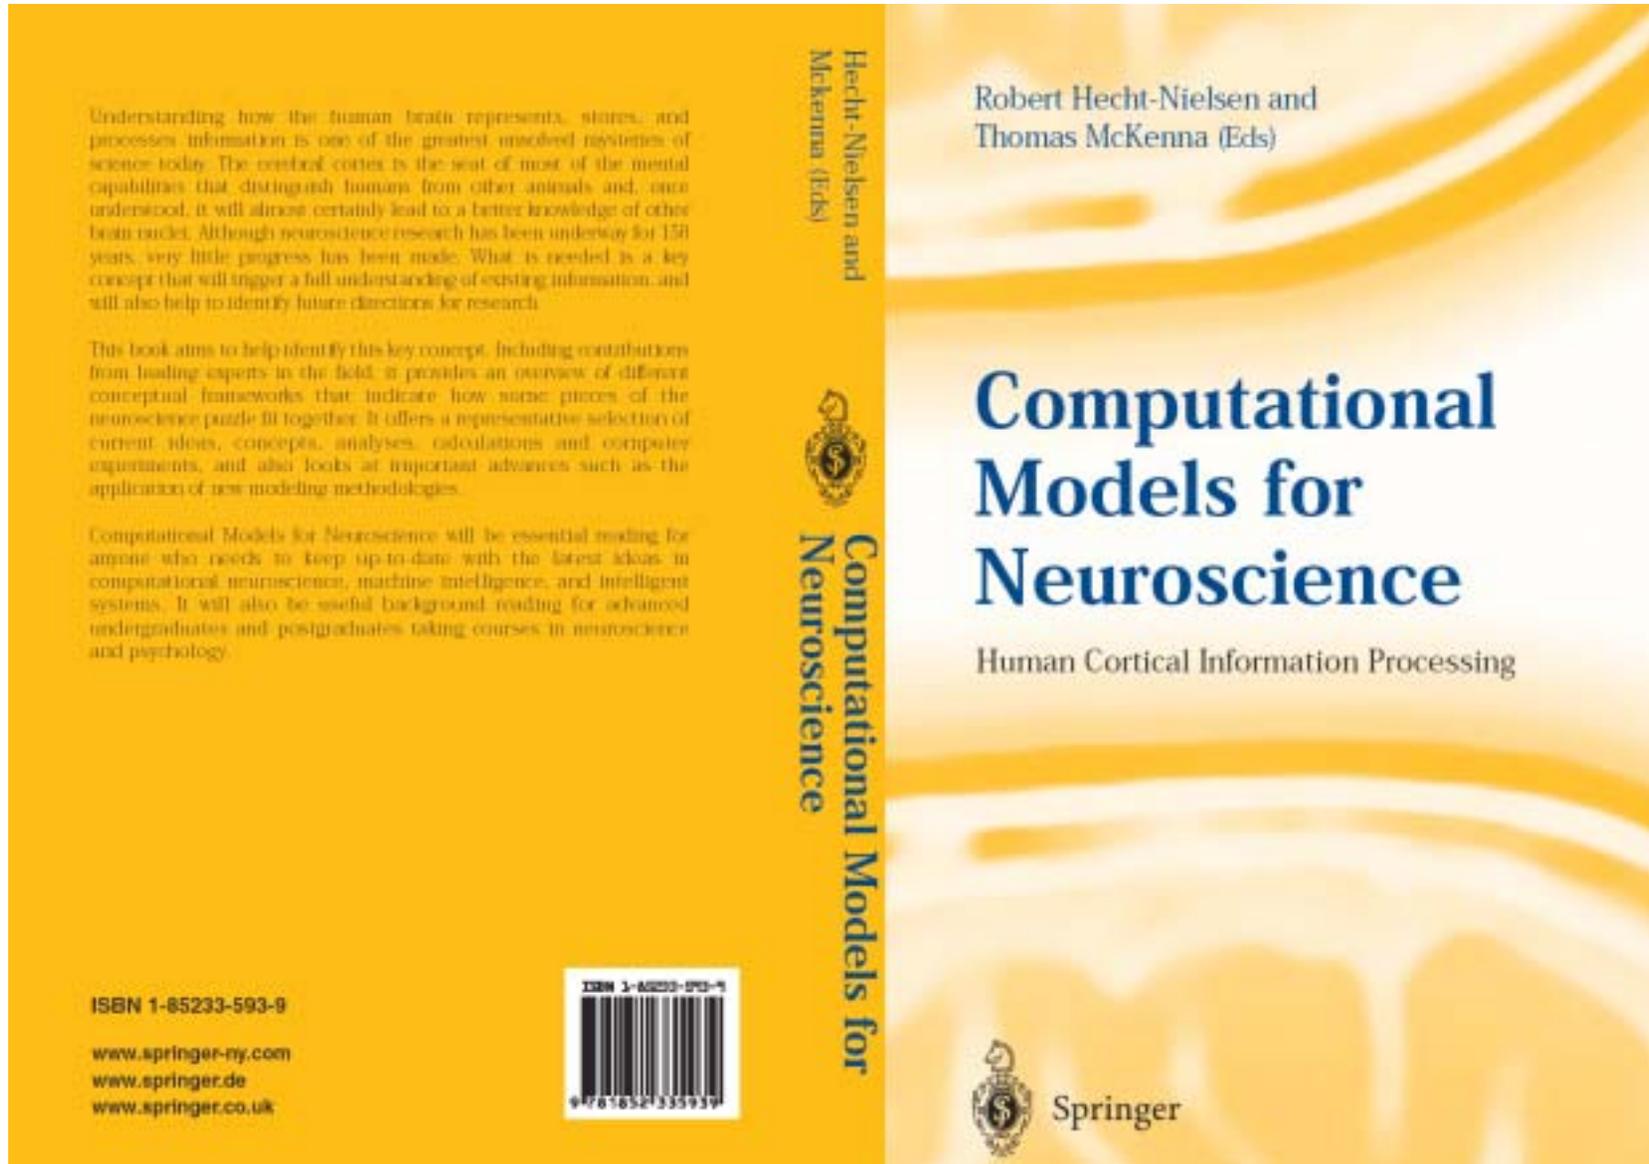

## Context Driven Family Disambiguation

# Education

- *Training* is the process of exposing a brain to a sequence of selected examples in an information environment.
- *Education* is where a brain is exposed to carefully selected examples with side information that indicates acceptable variants that can be used with each construct.
- Training depends upon the raw environmental frequency of exposure to decide what to learn.
- Education demands that everything which is presented is learned and ensures that obvious variants (not superceded by explicitly learned exceptions) will be handled similarly.

# Reference

Understanding how the human brain represents, stores, and processes information is one of the greatest unsolved mysteries of science today. The cerebral cortex is the seat of most of the mental capabilities that distinguish humans from other animals and, once understood, it will almost certainly lead to a better knowledge of other brain matter. Although neuroscience research has been underway for 150 years, very little progress has been made. What is needed is a key concept that will trigger a full understanding of existing information, and will also help to identify future directions for research.

This book aims to help identify this key concept. Including contributions from leading experts in the field, it provides an overview of different conceptual frameworks that indicate how some pieces of the neuroscience puzzle fit together. It offers a representative selection of current ideas, concepts, analyses, calculations and computer experiments, and also looks at important advances such as the application of new modeling methodologies.

Computational Models for Neuroscience will be essential reading for anyone who needs to keep up-to-date with the latest ideas in computational neuroscience, machine intelligence, and intelligent systems. It will also be useful background reading for advanced undergraduates and postgraduates taking courses in neuroscience and psychology.
